

JAVA

Introduction to Java.

What is Java?

Java is a programming language which is used to create an application.

What is program?

It is just an instruction which is used to create an application.

What is programming language?

The language which is used to write the program is called as programming language / high level language.

Example: Java, python, C#, php,, ruby.

What is an application?

It is the collection of programs or set of instruction called as application.

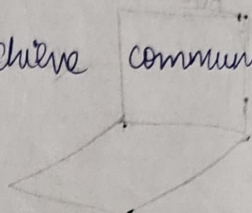

Types of application:

There are 3 types of application:

- * Stand alone application
- * web application
- * client-server / module application.

What is language?

* It is just a source to achieve communication b/w the two parties.

* We are having 3 types of language i.e

- (1) Binary language / low-level language
- (2) Assembly level lang / mid-level lang
- (3) High-level language / programming lang.

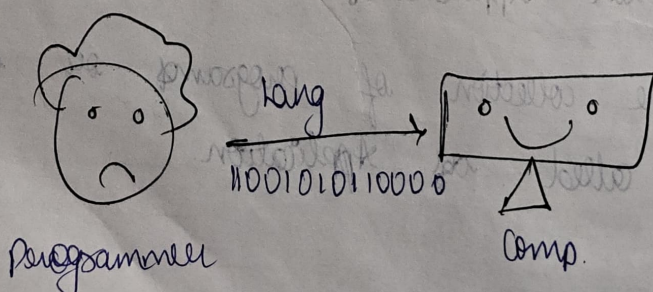

(1) Binary language:

* It is the language which contains 0 & 1.

* It is the only one language which is understandable by the computer.

* The level of the language is not easy to understand by the programmer.

Therefore there is a need of another language for better communication.

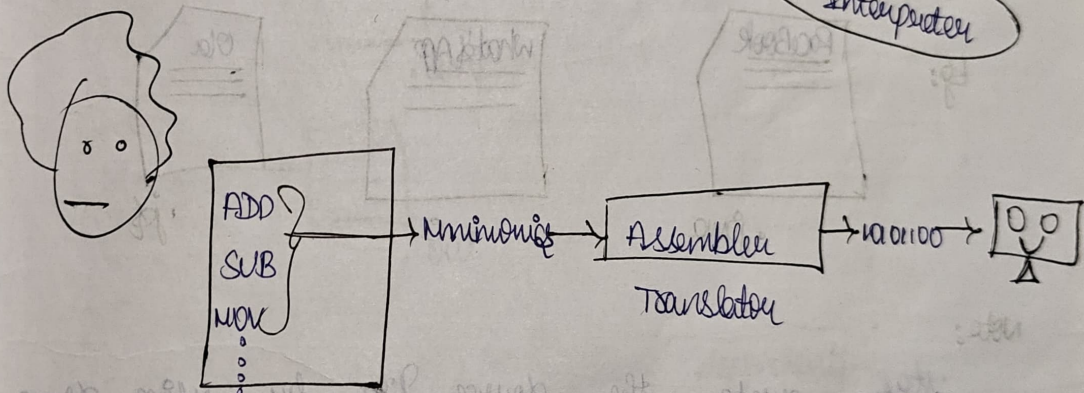

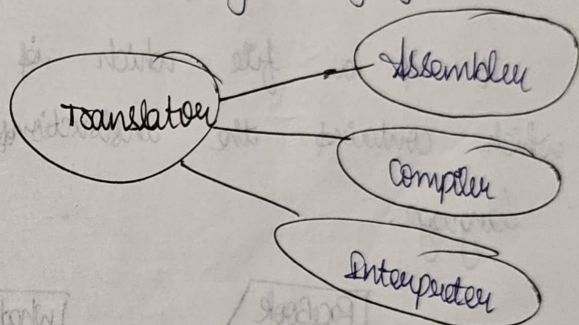

Q) Assembly level language:

- * It contains some pre-defined words called as mnemonics.

- * Assembly level language is partially understandable by the programmer. Therefore there is a need of another language.

- * Here we use assembler to translate from Assembly level lang into Binary language.

(3) High level language / programming lang:

- * It is programmer friendly language.

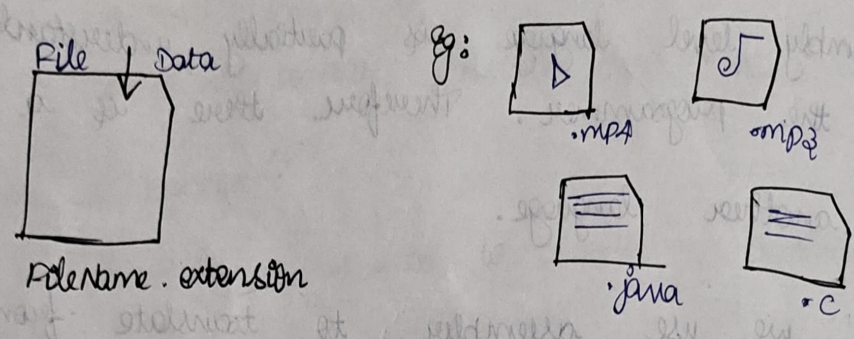

- * Here we use the translator or compiler to convert high level language into low level lang.

- * We can create complex application by using high level lang.

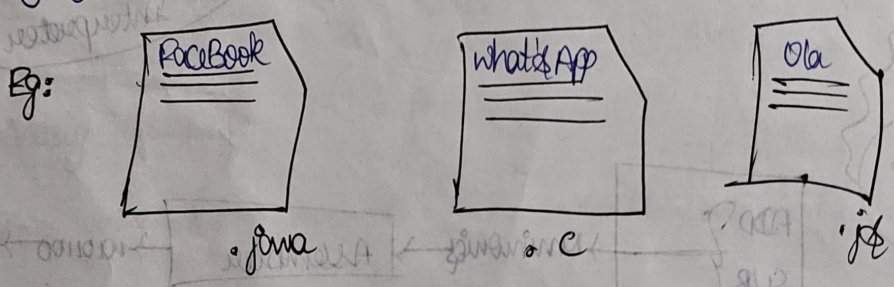

FILE:

* It is just a container which is used to store the data permanently.

What is Source File?

It is a file which is created by the programmer which contains the instructions written in high level language.

Note:

We can create the source file by using some text editor and IDE which is given below:
